Of a pale fuscous colour, with a distinct yellowish median line on the prothorax: the head is yellowish, with two elongate fuscous spots, which extend to the margin of the prothorax, in this respect differing from the common British species C. virescens of Pictet, to which it is very closely related; in C. virescens these spots are of a nearly circular form : the wings are lyaline, very shining, and tinged with yellow at the base, with scarcely any admixture of green; the nervures of the fore wings, and those of the apex of the hind wings, are brown.
Inhabits Canada, \&c. Taken by Messrs. Doubleday and Foster, at Trenton Falls. The difference between this and the British cognate species, considered independently of the widely-removed localities, is quite insufficient for the establishment of a species.

## Genus.-Sialis, Latreille.

Sialis infumatus. Nigra, alis vix hyalinis, nigro-punctatis, basi procipue infuscatis. (Corp. long. 3 unc.; alar. dilat. • 8 unc.)
This species differs principally from Sialis lutarius in the dark shade, approaching to black at the base of the fore wings : the entire body is black, including the antennæ and legs, and the wings are scarcely transparent, and thickly sprinkled with minute black dots. Inhabits North America. A single specimen taken by Mr. Doubleday at Trenton Falls.

> Art. LI.-On the Genus Cerapterus of Swederus. By J. O. Westwood, F.L.S.

This extraordinary genus of Coleopterous insects was established sixty years ago (1788) by Swederus, who described a single species, C. latipes. To these Donovan added another from New Holland, C. MacLeaii, and I described a third in my Monograph on the Paussida, under the name of C. Horsfieldii; without, however, being quite certain of its specific difference from C.latipes. In the last part of the Transactions of the Entomological Society, I figured an Australian species from the collection of M. Gory, which, judging from the acknowledged inaccuracy of Donovan in minute points of organization, I regarded, but doubtingly, as identical with
C. MacLeaii. Mr. MacLeay, himself the possessor of the individuals described by Swederus and Donovan, has in the first portion of the Annulosa of Dr. Smith's work, published a memoir upon this genus, (adding another species,) upon which I shall take the liberty to make a few remarks.

Of the characters given by Mr. MacLeay of the genus, we find the tarsi described as tetramerous and filiform. In M. Gory's insect they are decidedly pentamerous, which is the typical structure of the family; and the figures given by Mr. MacLeay represent the basal joints as broad and pulvillose. The other characters which he has given of the genus appear almost verbally extracted from those given by me in the Linn. Trans., although he is pleased to remark upon the extreme inaccuracy of previous writers upon the genus.

Mr. MacLeay has divided the genus (which, in accordance with his new system of nomenclature, must be called Cerapterinus,) into two subgenera, the characters of which may thus be contrasted:-

Subgenus Cerapterus, Swed.
Caput thorace angustius, collo brevi, oculis mediocribus:
Thorax latior quam longus lateribus dilatatis rotundatis:
Scutellum mediocre :
Elytra abdomine vix breviora apice subrotundata :
Tibix lateribus parallelis apice truncatis haud bispinosis:
Tarsi intra tibiarum apices excavatos retractiles.
Tropical, Asia and Africa.

Subgenus Arthropterus, ${ }^{a}$ MacLeay.
Caput thorace haud angustius, collo conspicuo, oculis magnis.
Thorax longior quam latus subquadratus.
Scutellum minimum.
Elytra angusta parallela apice truncata abdomine breviora.
Tibiæ lateribus haud parallelis apice bispinosis.
Tarsi intra tibiarum 'apices excavatos haud retractiles.
New Holland.

In the first of these subgenera are placed C. latipes, Horsfieldii, and Smithii, MacL.; and in the second MacLeaii, and M. Gory's species, of which Mr. J. Curtis possesses a specimen, noticed by Mr. MacLeay. It will be seen that these two subgenera are founded, not upon the variations of the trophi, (which are not described,) but almost entirely upon mere outline.

In the other Paussida, I have, however, clearly shown that external outline is valueless as a character, whilst the variation in the trophi led to the establishment of the genus Platyrho-

[^0]palus. The armature of the tibie is a more tangible character, but Mr. MacLeay has either shown that he deemed it as of no value, or has dreaded the establishment of a third subgenus for the reception of $C$. Smithii, "which differs from all the other species in this respect. In like manner M. Gory's species will not enter into the subgenus Arthropterus, as described by MacLeay, so that its characters must be modified, and which will render the following distribution of the species necessary:

## Subgen. I.-Cerapterus.

Thorax latissimus lateribus rotundatis: antennce latissimce lateribus serratis, articulo ultimo maximo: elytra abdomen tegentia: tibice spina nulla interna.
Habitat Asia.
Sp. 1. The original C. latipes of Swederus, which Mr. MacLeay characterizes thus:-" $C$. piceus, elytris maculâ apicali flavescente subrotunda antice quadridentata postice lobata, antennis rufis, articulo ultimo in tuberculum ad basim elevato:" and

Sp. 2. The species which I doubtingly described as C. latipes, suggesting that if distinct it should receive the name of $C$. Horsfieldii. Mr. MacLeay, however, although stating this, gives the reference to my name, C. Horsfieldii, with a mark of interrogation. Mr. MacLeay's character of this species is, " $C$. piceus, thorace antice emarginato, elytris maculâ apicali flavescente haud rotundata literam $Y$ quodammodo simulante."

## Subgen. II.-Orthopterus, Westwood.

Thorax latus (capite haud duplo latior): antennce longiores sublata plance lateribus subrectis, articulo ultimo mediocri: elytra abdomen tegentia : tibice spino apicali intus instructa. Habitat Africa.

Sp. 3. O. Smithii, Westw. C. nigro-piceus, subnitidus : elytris maculâ fulvâ, thorace latioribus et fere quintuplo longioribus. (Long. corp. lin. $7 \frac{1}{2}$.)
Habitat South Africa, within the tropic of Capricorn.
Cer. Smithii, MacLeay, Illustr. Ann. So. Africa, p. 74, pl. 4, fig. superior sinistra. (Mr. MacLeay's figures are not numbered.)

## Subgen. III.-Arthropterus, MacLeay.

Caput thorace haud angustius : thorax subquadratus : antenna sublata, articulo ultimo mediocri : elytra angusta, abdomine breviora : tibice apice bispinosce :b angulo externo acutissimo.
Habitat New Holland.
Sp. 4. A. MacLeaii, Donov. A. rufo-brunneus: thorace subconvexo postice angustiore, angulis anticis rotundatis : disco medio vix canaliculato.
A. MacLeaii, MacLeay op. cit. p. 75.

Subgen. IV.-Phymatopterus, Westwood.
Depressiusculus : caput thorace angustius: thorax cordato-truncatus medio longitudinaliter impressus: antennce latce: elytra oblongo-quadrata angulo externo apicali tuberculo munita: tibia lata, interne spinis duabus armata anguloque externo rotundato : tarsi distincte 5 -articulati.
Habitat New Holland.
Sp. 5. P. piceus. Piceus nitidus, antennis pedibusque rufopiceis, punctis minutissimis irregularibus. (Long. corp. lin. 5.)
Syn. Cerapterus MacLeaii, Westw. in Trans. Ent. Soc. Vol. II. p. 95. pl. X. fig. 17.
In the collections of Messrs. Goryc and J. Curtis.
Mr. MacLeay states that his brother had recently captured Cerapterus MacLeaii in the nests of ants; and moreover remarks, that when alive they had the power of exploding, after

[^1]the manner of the Brachini; the former of which circumstances was also observed by M.Verreaux in the Paussi of the Cape ; and I noticed in my Monograph, that a correspondent of M. Dupont had observed the crepitating powers of $P$. excavatus, Westw.

In proposing the separation of these four subgenera from Cerapterus, I have no hesitation in regarding them as of equal value. If the genus is to be dismembered as proposed by Mr. MacLeay, it appears to me to be necessary, in order to preserve an uniformity of value in the characters, that C. Smithii and C. piceus should be regarded as equally distinct with $C$. MacLeaii.

As to the circular progression of the Paussida, neither previously nor at the present time do I conceive it established. Mr. MacLeay proposes commencing with the true Paussi, thence to Platyrhopalus; P. Mellii leading to Cerapterus latipes, and Cerapterus MacLeaii to Pentaplatarthrus, from which he returns to Paussus. ${ }^{\text {" }}$ It is necessary, however, in order to maintain this circularity, that the other genera placed in the family must be got rid of, "since, if inserted in the above circular series, they appear to interrupt it."

The genera Hylotorus and Trochoideus are accordingly removed from the family; and I presume that my new genus Lebioderus will be similarly dealt with by Mr. MacLeay; because, although evidently intermediate between Platyrhopalus and Cerapterus, it interferes with the passage between Platyrhopalus Mellii, and Cerapterus latipes. Hylotorus, moreover, has so entirely the habit of the family, that, without more decisive proof to the contrary, it ought evidently to be retained in the family. As to the relations of Trochoideus, suggested by Mr. MacLeay, with Myrmecoxenus and other genera, such as Cryptophagus, it will be seen by my characters and figures given of it in the Trans. Ent. Soc. Vol. II. p. 96, that it has no relation therewith, but is, on the contrary, closely allied to Endomychus.

Mr. MacLeay's observations upon the relations of the family, appear to me to be entirely unfounded. He says that I seem to have been "the first to suspect the affinity of Cryptopliagns

[^2]to the Paussido, but that I have not expressed myself very clearly on the subject." It would have been extraordinary indeed if I had done so, because I never entertained such an opinion. I have said, repeatedly, that I considered the Paussidec most nearly allied to the aberrant Cucujida, such as Catogenus, Clinidium, \&cc. ; and I have seen no sufficient grounds for altering this opinion; for as to the relation of the Paussida with the Pselaphider, which Mr. MacLeay notices, nothing appears to me more unnatural. Claviger is found in ants' nests, and is anomalous in its antennæ, \&c; and Paussus agrees with it in both these respects; but no two groups can be more widely apart. It would have been quite as natural to assert the relation of the Paussida with the Ozence; for the latter crepitate, their bodies are polished, and their elytra are furnished with tubercles at the outer posterior angles, as in the Paussi.

In conclusion, as I know that I have the support of every entomologist, in having " vented a great deal of virtuous indignation" at the little care with which the Linnæan cabinet of insects has been preserved, 1 can but regret that Mr. MacLeay should have considered my observations upon the subject as uncalled for. ${ }^{\text {d }}$

Art. LII.-Description of some new Genera of Coleoptera in the Author's Collection. By W. E. Shuckard, Vice-President of the Entomological Society, and Librarian of the Royal Society.

The following descriptions of some new genera of Coleoptera which I possess, I forward, hoping they may be acceptable. Although adverse to scattered descriptions in general, I was unwilling to let the fine Eurhamphus step into the world alone; and I could not resist describing this, as my talented young friend, W. Spry, Esq., had favoured me with the accompanying beautiful drawing of it, which I am sure you will consider an embellishment to the Magazine.

[^3]
[^0]:    a Upon what character can Mr. MacLeay, (who speaks so harshly of names proposed by others,) have established this name?

[^1]:    ${ }^{\text {b }}$ Mr. MacLeay employs the term "bispinose," by which I presume we are to infer that the tibiæ have one internal spur and one external spine-at least they are so represented in the figure of $A$. MacLeaii; but the figure of the leg of C. Smithii has also one spur and one external spine, and yet it is described as "having only one spine at the extremity of the tibia."
    ${ }^{\text {c }}$ In addition to M. Gory's specimen, Donovan notices that another species of Cerapterus was communicated by M. Fichtel to the Royal Museum of Vienna, making at least two specimens of the genus in continental collections. It is possible, however, that the insect mentioned by Donovan may be that described by Kollar under the name of Paussus bifasciatus. (See Trans. Ent. Soc. Vol. II. p. 90.) The singular structure of the antennx of this species will probalily render the establishment of another subgenus requisite.

[^2]:    ${ }^{\text {d }}$ It will be seen that I pointed out this succession of the genera in my Monograph (p.616), commencing with Pentaplatarthrus, thence to the Paussi and Platyrhopali, which I regarded as evidently leading to the Cerapteri, considering Pentaplatarlhrus intermediate between Paussus and Ceraplerus (p. G18).

[^3]:    ${ }^{\text {d }}$ Mr. MacLeay erroneously gives to my observations an extension which they will not bear. It is not to the "Paussi presented to Latreille" by Mr. MacLeay, sen. that I alluded, but expressly to the single Linnæan specimen of Paussus microcephalus which las disappeared from the Linnæan Cabinet.
